# **Documentation for Web Data Analysis**

Somesh Kumar

## 1. Introduction

This project analyzes web traffic data from a website. The goal is to explore various metrics such as visits, page views, time spent on pages, bounces, and exits. The analysis includes statistical summaries, correlation analysis, and visualizations like scatter plots, bar plots, and heatmaps to help understand how different web metrics are related to each other.

## 2. Data Loading and Initial Exploration

The first step in the analysis is to load the dataset. The dataset is stored as a CSV file, which is read into a DataFrame using the **Pandas** library. Once the data is loaded, we inspect the first few rows to understand the structure of the dataset (e.g., column names, data types, and the first few entries).

We also check the data types of each column to ensure that they match the expected type (e.g., numeric, string). For example, we expect columns like Visits, Bounces, and Timeinpage to be numeric, while columns like Sourcegroup and Continent might be categorical.

Additionally, we check for any missing values (NaN) in the dataset. This is important because missing values can affect the accuracy of our analysis. If missing data is found, it will need to be addressed before performing further analysis.

## 3. Descriptive Statistics

To get a better understanding of the data, we calculate summary statistics for all numerical columns. This includes:

- **Mean**: The average value of each numeric column.
- **Median**: The middle value of each numeric column when sorted.
- Standard Deviation: A measure of how spread out the values are around the mean.
- Minimum and Maximum: The smallest and largest values in each numeric column.

We also calculate **skewness**, which tells us if the data is symmetrically distributed or if it's skewed in one direction (positive skew means data is skewed right, negative skew means data is skewed left).

These statistical summaries provide a foundation for understanding the general behavior of each variable.

# 4. Correlation Analysis

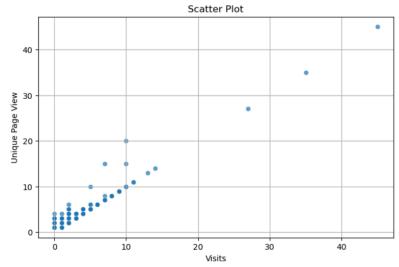

Correlation analysis helps us understand how strongly two or more variables are related. In this case, we look at the relationship between Uniquepageviews and Visits. The **correlation coefficient** tells us if these variables are strongly, moderately, or weakly related. A positive correlation means that as one variable increases, the other also increases. A negative correlation means that as one variable increases, the other decreases.

We visualize this relationship through a **scatter plot**, which displays the data points for Visits and Uniquepageviews on a two-dimensional plane. This helps in identifying any linear relationship between the variables.

### Result

Correlation Coefficient: 0.8144457070734599

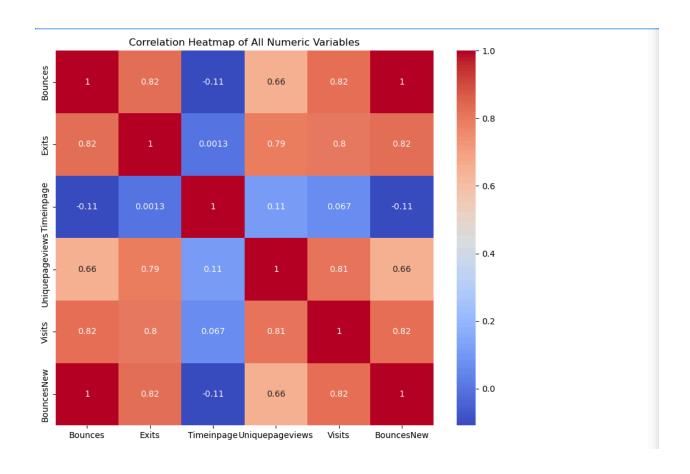

The correlation between unique page views and visits is strong (correlation coefficient = 0.81).

# 5. Heatmap for Correlation Between All Numeric Variables

A **correlation heatmap** is generated to show the correlation between all numeric columns in the dataset. Each cell in the heatmap represents the correlation between two variables, with colors indicating the strength of the correlation (red for high positive correlation, blue for high negative correlation, and white for no correlation).

This heatmap provides a visual summary of how different variables interact with each other. For instance, if Timeinpage and Exits have a strong negative correlation, it might suggest that users who spend more time on the page are less likely to exit quickly.

## 6. Time on Page Analysis

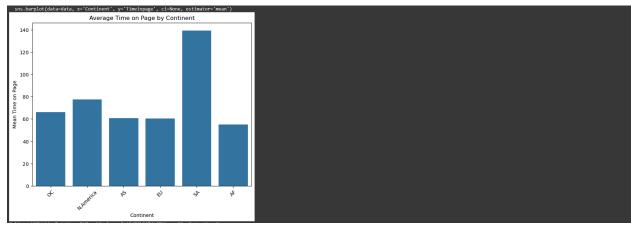

Next, we analyze the Timeinpage column to understand how it correlates with other variables. First, we convert the Timeinpage column to numeric values (in case it contains any non-numeric entries). After conversion, we check the correlation of Timeinpage with other variables in the dataset, such as Visits, Exits, Bounces, and others.

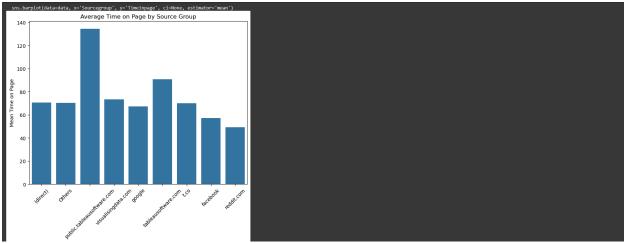

We also examine how the average Timeinpage varies across different categories, such as by **Continent** or **Sourcegroup**, by creating **bar plots**. These plots show the mean time spent on pages for each category, which can help identify geographic or source-related trends.

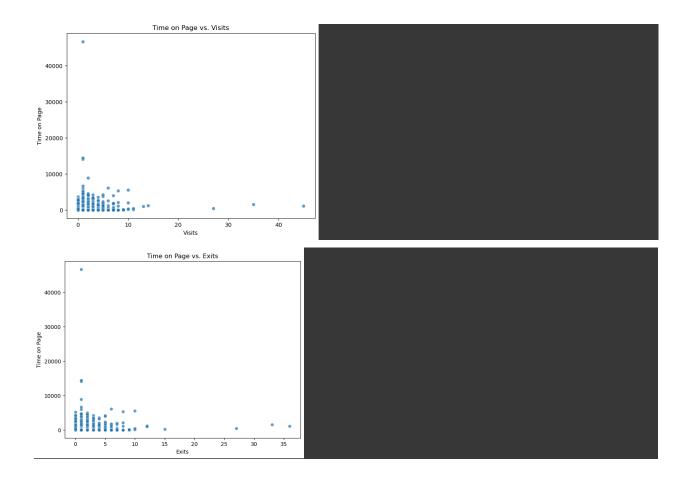

Additionally, we create scatter plots to examine the relationship between Timeinpage and other continuous variables (like Visits and Exits). This allows us to visually explore whether there's a pattern between how much time a user spends on a page and their likelihood of exiting or how many pages they visit.

Correlation of variables with Time on Page:

Timeinpage 1.000000
Uniquepageviews 0.114593
Visits 0.066650
Exits 0.001325
Bounces -0.109106
BouncesNew -0.109106
Name: Timeinpage, dtype: float64

# 7. Bounces Analysis

The Bounces column refers to users who land on a page and leave without interacting further. We analyze how Bounces correlate with other variables, such as Timeinpage and Visits. A positive correlation between Bounces and Exits might suggest that users who exit the page are more likely to bounce.

We visualize this relationship with **bar plots** (showing average bounces by Continent and Sourcegroup) and a **scatter plot** (showing bounces vs. time spent on the page). These visualizations help understand if there are specific regions or sources where users tend to bounce more frequently.

```
Correlation of variables with Bounces:

Bounces 1.000000

BouncesNew 1.000000

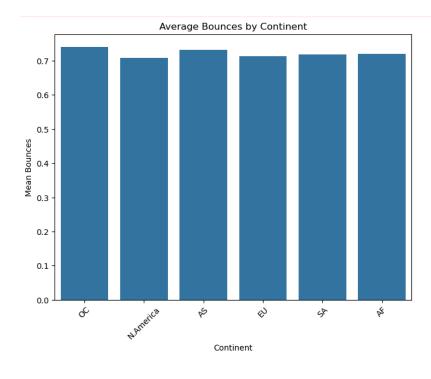

Exits 0.824912

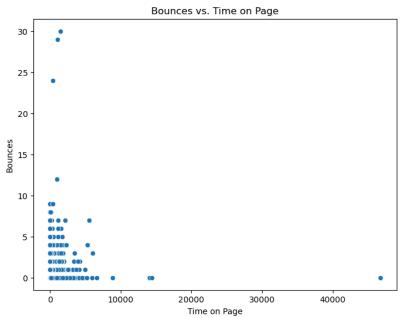

Visits 0.819343

Uniquepageviews 0.659101

Timeinpage -0.109106

Name: Bounces, dtype: float64
```

## 8. Conclusion

This analysis provides a deep dive into the behavior of website visitors. By calculating correlations, examining descriptive statistics, and visualizing relationships between key metrics, we can gain insights into how different aspects of web traffic are connected.

For example, understanding the correlation between Visits and Uniquepageviews can help us determine how traffic patterns relate to user engagement. Similarly, by analyzing Timeinpage, Bounces, and Exits, we can uncover patterns related to user retention and abandonment.

These insights can guide website optimizations and inform business decisions on where to focus marketing or improve user experience.
